Abstract. *The one-dimensional Schrödinger equation on the entire axis with an exponentially confining potential is considered. The asymptotic behavior of the eigenvalues is found.*

Keywords. Schrödinger equation · confining potential · eigenvalues · modified Bessel function of the second kind

Mathematics Subject Classification (2010): 34A55, 34B24, 58C40, 47E05

1 Introduction and main results

Confining potentials are used as a model of coupled systems with strong localization. Among other models, we note the linear potential and the harmonic oscillator potential, which describe confinement with a quadratic and linear force, respectively (see [5, 7, 8, 11]). Recently, exponentially confining potentials have also grown in great interest (see [2]).

Consider a one-dimensional Schrödinger potentials equation of the form

$$-y'' + (A_1 e^x + A_2 e^{-x}) y = \lambda y, \quad -\infty < x < +\infty, \quad (1.1)$$

where A_1 and A_2 are positive constants and λ is the spectral parameter. The left side of equation (1.1) generates a self-adjoint operator $L(A_1, A_2) = -\frac{d^2}{dx^2} + A_1 e^x + A_2 e^{-x}$ in the space $L_2(-\infty, +\infty)$. Since $A_1 e^x + A_2 e^{-x} \rightarrow +\infty$ for $x \rightarrow \pm\infty$, the spectrum of the operator L consists [4] of simple real eigenvalues λ_n , $n = 0, 1, 2, \dots$, condensing to $+\infty$, with $\lambda_n \geq \inf_{-\infty < x < +\infty} (A_1 e^x + A_2 e^{-x}) = 2\sqrt{A_1 A_2} > 0$.

In this paper, we study the asymptotic behavior of the eigenvalues λ_n , $n = 0, 1, 2, \dots$ for $n \rightarrow \infty$.

Let us formulate the main result of this work.

Theorem 1.1 For the eigenvalues λ_n , $n = 0, 1, 2, \dots$ of the operator $L(A_1, A_2)$ the asymptotic formula

$$\lambda_n \sim \frac{\pi n}{2 \ln n}, \quad n \rightarrow \infty. \quad (1.2)$$

2 Proof of the theorem

Consider the following boundary value problem

$$-y'' + \alpha e^x y = \lambda y, \quad -\infty < x < +\infty, \quad (2.1)$$

$$y(0) \cos \beta + y'(0) \sin \beta = 0, \quad (2.2)$$

where $\alpha > 0$ and β is a real number. Consider a self-adjoint operator $L_0(\alpha)$ generated in the space $L_2(0, +\infty)$ by the left side of equation (2.1) and boundary condition (2.2). Since $e^x \rightarrow +\infty$ for $x \rightarrow +\infty$, the spectrum of the operator $L_0(\alpha)$ is discrete [4] and has a unique limit point at infinity. Denote by $\mu_n = \mu_n(\alpha)$, $n = 0, 1, 2, \dots$ the eigenvalues of the operator $L_0(\alpha)$. Obviously $\mu_n \geq \inf_{0 < x < +\infty} \alpha e^x = \alpha > 0$. It is known [1, 3] that equation (2.1) has a solution $\psi(x, \lambda)$, which can be represented as

$$\psi(x, \lambda) = K_{2i\sqrt{\lambda}} \left(2\sqrt{\alpha} e^{\frac{x}{2}} \right),$$

where $K_\nu(z)$ is a modified Bessel function of the second kind (see [1, 3]), i.e. solution of the equation

$$z^2 u'' + z u' - (z^2 + \nu^2) u = 0.$$

It is also known [1, 3] that for each $z > 0$ the function $K_\nu(z)$ is an entire function of index ν and the integral representation

$$K_{i\lambda}(z) = \int_0^\infty e^{-zcht} \cos \lambda t dt, \quad |\arg z| < \frac{\pi}{2}, \quad \lambda \in C$$

is valid. Therefore, for every fixed x , $0 \leq x < +\infty$, the solution $\psi(x, \lambda)$ serves as an entire function with respect to λ . Further, the following asymptotic formula is true [1]

$$K_\nu(z) = \sqrt{\frac{\pi}{2z}} e^{-z} (1 + O(z^{-1})), \quad z \rightarrow \infty.$$

This implies that for every fixed λ the solution $\psi(x, \lambda)$ belongs to the space $L_2(0, +\infty)$. Whence it follows that the eigenvalues of the operator $L_0(\alpha)$ coincide with the zeros of the function $\Psi(\lambda) = \psi(0, \lambda) \cos \beta + \psi'(0, \lambda) \sin \beta$.

Let us now study the asymptotic behavior of the eigenvalues of the $L_0(\alpha)$. Since the function $q(x) = \alpha e^x$ satisfies all conditions of Theorem 7.3 from the monograph [9] (see also [10]), we have

$$\int_0^{\ln \alpha^{-1} \mu_n} \sqrt{\mu_n - \alpha e^x} dx \sim \pi n, \quad n \rightarrow \infty. \quad (2.3)$$

Further, note that

$$\begin{aligned} \int_0^{\ln \alpha^{-1} \mu_n} \sqrt{\mu_n - \alpha e^x} dx &= \int_a^{\mu_n} t^{-1} \sqrt{\mu_n - t} dt \\ &= \mu_n \int_a^{\mu_n} \frac{\mu_n}{t} \sqrt{1 - \frac{t}{\mu_n}} d \frac{t}{\mu_n} = \mu_n \int_{\alpha \mu_n^{-1}}^1 u \sqrt{1 - u} u du. \end{aligned} \quad (2.4)$$

Since the function $G(u) = 2\sqrt{1-u} - \ln(1 + \sqrt{1-u}) + \ln(1 - \sqrt{1-u})$ serves as an antiderivative function $g(u) = u^{-1}\sqrt{1-u}$, then from formula (2.4) we have

$$\int_0^{\ln \alpha^{-1} \mu_n} \sqrt{\mu_n - \alpha e^x} dx = \mu_n \ln \mu_n \left(1 + O\left(\frac{1}{\ln \mu}\right) \right), \quad n \rightarrow \infty.$$

Comparing this relation with (2.3), we obtain

$$\mu_n \ln \mu_n = \pi n [1 + o(1)], \quad n \rightarrow \infty.$$

If now we are looking for μ_n in the form $\mu_n = \frac{\pi n}{\ln \pi n} (1 + \varepsilon_n)$, then from the last equality it is easy to derive the relation $\varepsilon_n = o(1)$, $n \rightarrow \infty$. Therefore, for the zeros of the function $\psi(0, \lambda) = K_{2i\sqrt{\lambda}}(2\sqrt{\alpha})$, i.e. for the eigenvalues of the operator $L_0(\alpha)$ is true the following asymptotic equality

$$\mu_n \sim \frac{\pi n}{\ln n}, \quad n \rightarrow \infty. \quad (2.5)$$

We now introduce a self-adjoint operator $L_0(A_1, A_2)$, generated in space $L_2(0, +\infty)$ by the differential expression $l(y) = -y'' + (A_1 e^x + A_2 e^{-x})y$ and boundary condition (2.2). Further, setting $\alpha = \alpha_1 = \min\{A_1, A_2\}$ and $\alpha = \alpha_2 = \max\{A_1, A_2\}$, we find that

$$L_0(\alpha_1) \leq L_0(A_1, A_2) \leq L_0(\alpha_2).$$

Then, by virtue of the minimax principle (see [6]), we find that the eigenvalues λ_n^0 of the operator $L_0(A_1, A_2)$ satisfy the inequality

$$\mu_n(\alpha_1) \leq \lambda_n^0 \leq \mu_n(\alpha_2).$$

From the last inequality and (2.5) it follows that

$$\lambda_n^0 \sim \frac{\pi n}{\ln n}, \quad n \rightarrow \infty. \quad (2.6)$$

Consider now in the space $L_2(0, +\infty)$ the self-adjoint operators $L_D y = -y'' + A(e^x + e^{-x})y$, $y(0) = 0$ and $L_N y = -y'' + A(e^x + e^{-x})y$, $y'(0) = 0$, which are special cases of the operator $L_0(A_1, A_2)$. Let $\lambda_n(D)$ and $\lambda_n(N)$, $n = 0, 1, 2, \dots$ denote the eigenvalues of the operators L_D and L_N , respectively. Due to (2.6) we have

$$\begin{aligned} \lambda_n(D) &\sim \frac{\pi n}{\ln n}, \quad n \rightarrow \infty, \\ \lambda_n(N) &\sim \frac{\pi n}{\ln n}, \quad n \rightarrow \infty. \end{aligned} \quad (2.7)$$

Since the function $e^x + e^{-x}$ is even, the spectrum of the operator $L(A, A)$ coincides with the eigenvalues of the operators L_D and L_N . Setting $\hat{\lambda}_{2n} = \lambda_n(D)$, $\hat{\lambda}_{2n+1} = \lambda_n(N)$, $n = 0, 1, 2, \dots$, from (2.7) we obtain

$$\hat{\lambda}_n \sim \frac{\pi n}{2 \ln n}, \quad n \rightarrow \infty.$$

Then from the inequality

$$L(\alpha_1, \alpha_1) \leq L(A_1, A_2) \leq L(\alpha_2, \alpha_2)$$

and the minimax principle follows (1.2). Thus the theorem is proved.
